Could a fast model run a food stall?

120 decisions. 3 models. 6 shifts each.

One shift. Many ways to lose.

Profit, service, waste and waiting
pull the three stalls in different directions.

Every action changes the next decision.

Clean scenario · retained action-criteria prompt 1

1 Observe

Queue, stock, clock, mechanics, legal actions

2 Choose

Serve, cook, restock, promote or wait

3 Advance

Deliveries, spoilage and customers evolve

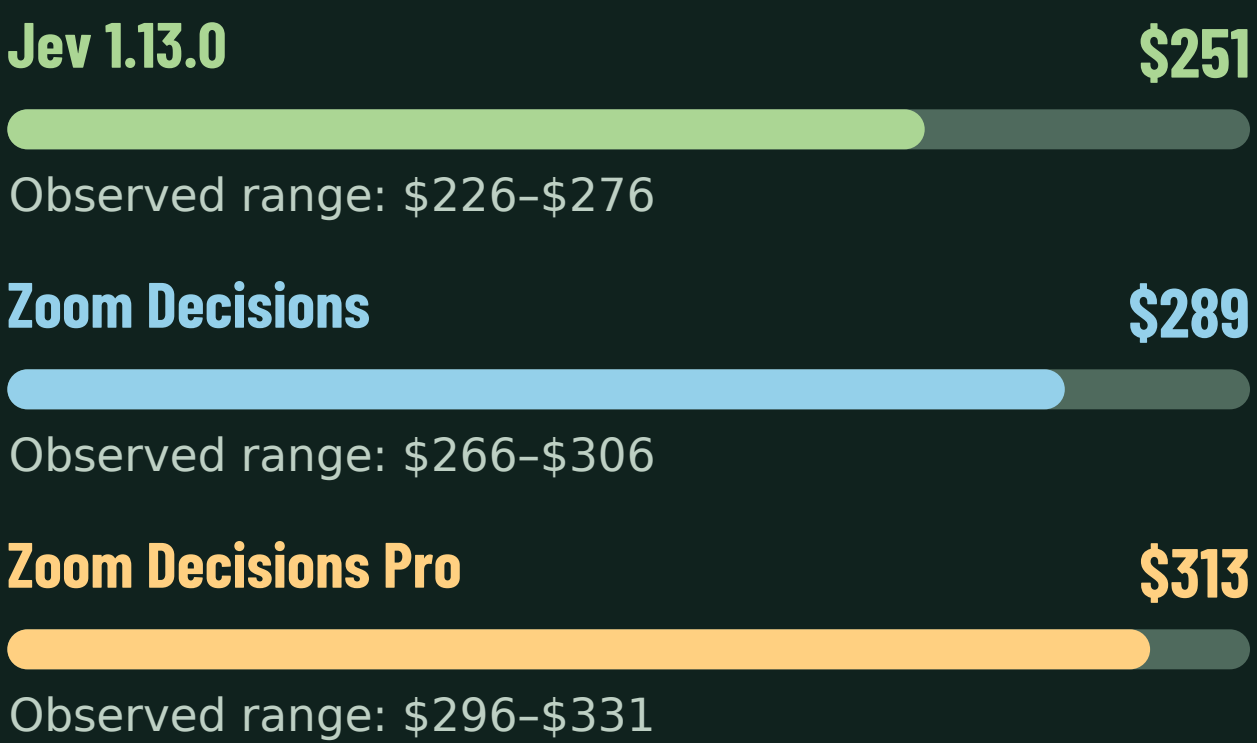

Six shifts per model

3 seeds × 2 repeats × 3 models = 18 trajectories

Profit and utility favored Pro.

Mean game profit per shift · n = 6 per model

Bars start at $0; game dollars exclude API fees.

6 / 6 **Pro led final utility too.**
Utility is the instructed objective.

Serving the most was not the whole score.

Mean per shift · n = 6 per model

	SERVED	WASTED	LEFT
Jev 1.13.0	86.3	4.0	39.0
Zoom Decisions	113.3	22.0	18.3
Zoom Decisions Pro	108.2	5.5	18.2

Zoom served more; Pro wasted less.

“Left” means customers who abandoned the queue.

A stockout does not mean the model chose WAIT.

Queue present, no ready food · ticks per shift
Shared 0–65 tick scale; six shifts per model

0 empty-pipeline WAITs with RESTOCK legal

These are simulated ticks, not API latency.

What these shifts can—and cannot—say.

6 / 6 Pro led profit and utility

6 / 6 Zoom served the most

7 rules fallbacks in 18 trajectories

6 invalid Jev responses; 1 Pro timeout.

Seed 23 is a separate run.

It reversed the Jev / Zoom profit order.

Three new seeds do not establish a general model ranking.

Effective for what?

For this simulator, prompt and demand schedule:

ZOOM DECISIONS PRO

Higher utility and game profit.

Mean $313 profit; 108 served; 5.5 wasted.

ZOOM DECISIONS

More customers served.

Mean 113 served; $289 profit; 22 wasted.

These are game outcomes, not API ROI.

Actual API fees and inference latency need separate measurement for economic or real-time effectiveness.

Judge the whole shift, not one move.

Follow the evidence.
